Inducció del part

Resultats primaris

Part vaginal < 24h
Part vaginal
Cesària (indicació)
Fase activa de part

Metodologia inducció

Prostaglandines (règims)
Oxitocina
Dilatació mecànica
Estimulació mugró

Test positiu

Punt de tall Bishop
Tipus de Bishop
Punt de tall CL
Altres paràmetres eco

!!!% nulipares i
% cesària!!!

Basic requirements:

- Multiparity
- Pregnancy >36 weeks
- Vertex
- Normal previous and present obstetric history
- Advance knowledge and permission of the patients
- After these criteria met, apply the pelvic score: ≥ 9 (noted dilation most important)

PELVIC SCORE					
	Cm	0	1-2	3-4	5-6
DILATATION		0	1	2	3
	%	0-30	40-50	60-70	80
EFFACEMENT		0	1	2	3
		-3	-2	-1 0	+1 +2
STATION		0	1	2	3
		Firm	Medium	Soft	
CONSISTENCY		0	1	2	
		Post.	Mid.	Ant.	
POSITION		0	1	2

OR=Odds Ratio

Validació externa de models predictius.

- **Peregrine et al.** includes maternal height, BMI, parity and cervical length as the predictors of Cesarean delivery.
- In this model the risk for Cesarean delivery is calculated as
- $100/(1 + \exp\{-[5.7311175 + (\text{risk score}/14.1)]\})$, where the risk score is: +43 for nulliparity, +26 for BMI ≥ 30 , +1 for each mm of cervical length and -1 for each cm of
- maternal height
- **Rane et al.** includes five prognostic variables: cervical length, parity, BMI, gestational age and maternal age.
- In this model the risk for Cesarean section was predicted by the following: risk (%) = $(\text{odds}/(1+\text{odds})) \times 100$, where odds = e^Y and $Y = 1.4404 + (0.0841 \times \text{cervical length in mm}) - (1.3834 \times (1 \text{ for parous women, } 0 \text{ for nullipara})) + (0.6125 \times (1 \text{ for BMI } \geq 30, 0 \text{ for BMI} < 30)) - (0.1314 \times \text{gestational age in weeks}) + (0.039 \times \text{maternal age in years})$.
- Verhoeven et al.. *Ultrasound Obstet Gynecol* 2009; **34**: 316–321.

Validació externa models predictius

We included 240 women in the study, of whom 27 (11%) had Cesarean delivery. The capacity of cervical length in the prediction of Cesarean delivery was limited.

In our study population, both prediction models overestimated the risk of Cesarean delivery.

Calibration was better for the Peregrine et al. model than for the Rane et al. model, and the two models had areas under the ROC curve of 0.76 and 0.67, respectively.

Conclusion : *Current models that predict the occurrence of Cesarean section after induction of labor have only a moderate predictive capacity when applied within a Dutch practice.*

▪ Verhoeven et al.. *Ultrasound Obstet Gynecol* 2009; **34**: 316–321.

Metaanàlisi Hartfield.

Cervical length predicted successful induction (likelihood ratio of positive test,

1.66; 95% confidence interval [CI], 1.20-2.31) and failed induction (likelihood ratio of negative test, 0.51; 95% CI, 0.39-0.67).

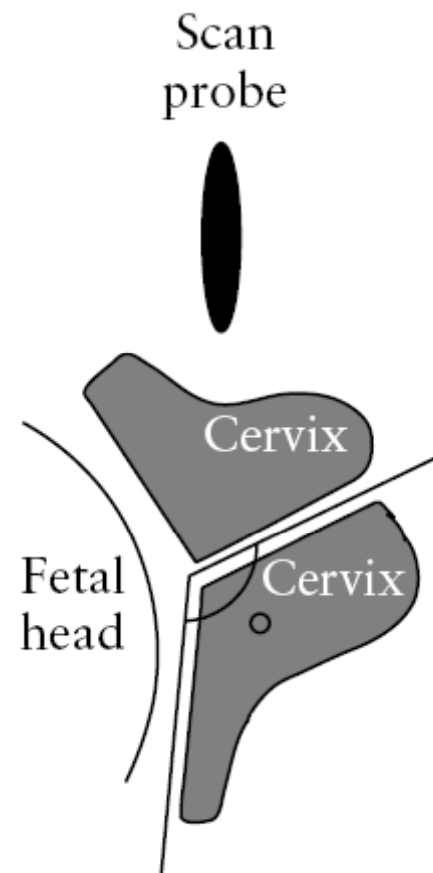

Cervical length did not predict any specific outcome (eg, mode of delivery).

HJ23

Hospital Joan XXIII

Rct Bishop vs CI

- *While 85% of women received prostaglandin in the Bishop score group, only 50% of them did in the transvaginal ultrasound group (P = 0.001).*
- *The interval to active phase, interval to delivery and rate of Cesarean section were similar in both groups*
- ***Menys necessitat de PGE2.***

Conclusions

- Tant el test de Bishop com la llongitud cervical per ecografia tenen una capacitat de predicció de l'èxit de la inducció limitada.
 - CL exit inducció
 - BS duració inducció
- La inclusió d'altres paràmetres ecogràfics millora parcialment els resultats.
- L'aplicació dels diversos models predictius en diferents poblacions no presenta els mateixos resultats.
- Els diferents punts de tall i criteris de resultat compliquen la comparació de resultats i la possible aplicació clínica.
